

Internet Appendixes A-2 and A-3 of the Paper ”Are Short-Lived Jobs Stepping Stones to Long-Lasting Jobs?”

Bart Cockx* and Matteo Picchio†

July 22, 2009

A-2 The Simulation Procedures

We now describe the steps involved in both the simulation to construct the goodness-of-fit statistics (Subsection 5.1) and the one to check the stepping stone hypothesis of short-lived jobs (Subsection 5.3).

A-2.1 The Simulation with regard to the Goodness-of-Fit

We first discuss a complication induced by the stock sampling of the data. This affects the specification of the distribution of unobserved heterogeneity from which vector-values are drawn and assigned to each sampled individual at the start of each simulation loop. Since all sampled individuals have already been unemployed for three quarters at the start of the observation period, the distribution of unobserved heterogeneity must be modified along the lines of the adjustment of the likelihood function. This means that the probability p_{im} that individual i is of type m and is therefore assigned the vector of location points $\hat{\mathbf{v}}_m \equiv [\hat{v}_{uem}, \hat{v}_{uam}, \hat{v}_{eem}, \hat{v}_{eum}, \hat{v}_{eam}]$ for $m = 1, \dots, \widehat{M}$ can be estimated by

$$\hat{p}_{im} = \frac{\widehat{S}_u(3|\mathbf{x}_{ui}; \widehat{\Theta}_u, \hat{\mathbf{v}}_{um}^1) \hat{p}_m}{\sum_{r=1}^{\widehat{M}} \widehat{S}_u(3|\mathbf{x}_{ui}; \widehat{\Theta}_u, \hat{\mathbf{v}}_{ur}^1) \hat{p}_r}, \quad (\text{A-5})$$

where $\widehat{M} = 4$ for men and $\widehat{M} = 5$ for women. Observe that this distribution depends on the values of the observed explanatory variables at the sampling date.

The simulation then proceeds according to the following steps:

*Sherppa, Ghent University, Tweekerkenstraat 2, B-9000 Gent, Belgium; UCLouvain (IRES), Louvain-la-Neuve; IZA, Bonn ; CESifo, Munich. E-mail: bart.cockx@ugent.be.

†IRES and Department of Economics, Université catholique de Louvain, Place Montesquieu 3, B-1348 Louvain-la-Neuve, Belgium. E-mail: matteo.picchio@uclouvain.be.

1. Draw a vector of parameter estimates assuming that the estimator is Normally distributed around the point estimates with a variance-covariance matrix equal to the estimated one.
2. Assign to each individual the value of the observed explanatory variables at the sampling date and a vector of unobserved characteristics drawn with the probability as given in Equation (A-5).
3. Simulate the transition from unemployment (u) to employment (e) and the endogenous censoring state (a) by a sequence of quarterly transition lotteries starting from the 4th quarter, which corresponds to the start of the observation period. These transition lotteries are based on the empirical counterparts of the probability of leaving state u for k ($k = e, a$), conditional on surviving in state u until the end of the previous quarter. Their form is given by Equation (A-4). In this process, the time-varying variables, for example the local unemployment rate, are adjusted to their new values at the beginning of each quarter.
4. If a transition to the censoring state a occurs, the simulation for that individual is halted. If there is a transition to employment e , assign new values to the unemployment rate and the spell specific time-varying variables. The age, quarter of entry, and household position of each individual are assigned the values as reported at the calendar time corresponding to the quarter of entry in the simulated employment spell. The vector of firm characteristics corresponds to that of the firm that was randomly drawn from the set of firms that hired workers with the same origin state (u or e) and elapsed duration in that origin state.¹
5. Simulate the transitions from the employment state and from all subsequent states according to a similar sequence of quarterly lotteries as described for the unemployment state in point 3 and adjust the time-varying explanatory variables according to the procedure described in point 4. In addition, in each new unemployment spell the amount of unemployment benefits is adjusted according to the rules, using information on the corresponding household position, age, and labour market history.
6. The simulation procedure is halted once the end of the observation period is reached, i.e. in December 2001, 13 to 16 quarters after the sampling date.
7. Repeat for each individual points 1 to 6 999 times to obtain 999 independent labour market histories for each sampled individual.

A-2.2 The Simulation with regard to the Stepping Stone Hypothesis

The simulation procedure goes as follows:

¹We also tried an alternative procedure in which we drew firm size and sector randomly from the corresponding marginal empirical distributions, but this resulted in very poor goodness-of-fit statistics.

1. Simulate the labour market history for all individuals in the sample as in Appendix A-2.1.
2. Retain only those individuals who entered a short-lived job within the first m quarters after graduation and who were not endogenously censored within d quarters after entering a short-lived job.
3. For each retained individual we re-simulate, conditional on not being endogenously censored,² $J = 100$ times the labour market history until the end of the observation window, once with and once without imposing the counterfactual job search strategy in which all short-lived jobs are rejected as a way out of the first unemployment spell after graduation. In the counterfactual case, the job-seeker who is imposed the rejection of a short-lived job is allowed to continue searching for new jobs in the same quarter.³
4. Calculate for each d up to $D = 8$ the empirical counterpart of the CAITT for each retained individual by taking the difference in the outcome variable between the two counterfactuals. This provides us with one estimation of the CAITT distribution.
5. Calculate and store the mean of the CAITT (which is an estimate of the CATT) and a number of selected percentiles of the CAITT distribution.
6. As to construct 95% empirical confidence intervals of the CATT and the selected percentiles of the CAITT distribution, we repeat steps 1 to 5 119 independent times.⁴

A-3 Further Descriptive Statistics and Estimation Results

This appendix displays descriptive statistics and estimation results not presented in the main text of our paper for the sake of brevity. Figure A-1 provides by gender an overview of the absolute frequencies of the first four labour market transitions, whereas Figure A-2 decomposes these absolute frequencies according to job durations. Table A-1 contains means and standard deviations of the time-varying variables at the beginning of the first five labour market spells. Tables A-2 and A-3 present descriptive statistics of short-lived jobs and long-lasting jobs. Tables A-4–A-8 comprise estimated parameters of the benchmark model not reported in the text. Table A-9 reports in panel (a) the mean and selected percentiles of the CAITT distribution for $m = 11$ and $d = 4$. Panel (b) displays the CAITT distribution when a long-lasting job is defined as a job lasting at least five quarters, with $m = 7$ and evaluation carried

²This conditioning is realized by adjusting the transition probability in Equation (A-4) in the following way

$$\frac{\left[1 - \exp \left\{ - \sum_{(j,k) \in \mathcal{J}} \theta_{jk}^s(t_s) \right\}\right] \times \frac{\theta_{jk}^s(t_s)}{\sum_{(b,c) \in \mathcal{J}} \theta_{bc}^s(t_s)}}{1 - \left[1 - \exp \left\{ - \sum_{(j,k) \in \mathcal{J}} \theta_{jk}^s(t_s) \right\}\right] \times \frac{\theta_{ja}^s(t_s)}{\sum_{(b,c) \in \mathcal{J}} \theta_{bc}^s(t_s)}},$$

where the denominator is the conditional set, i.e. the conditional probability of not ending the quarter in the endogenous censoring absorbing state a .

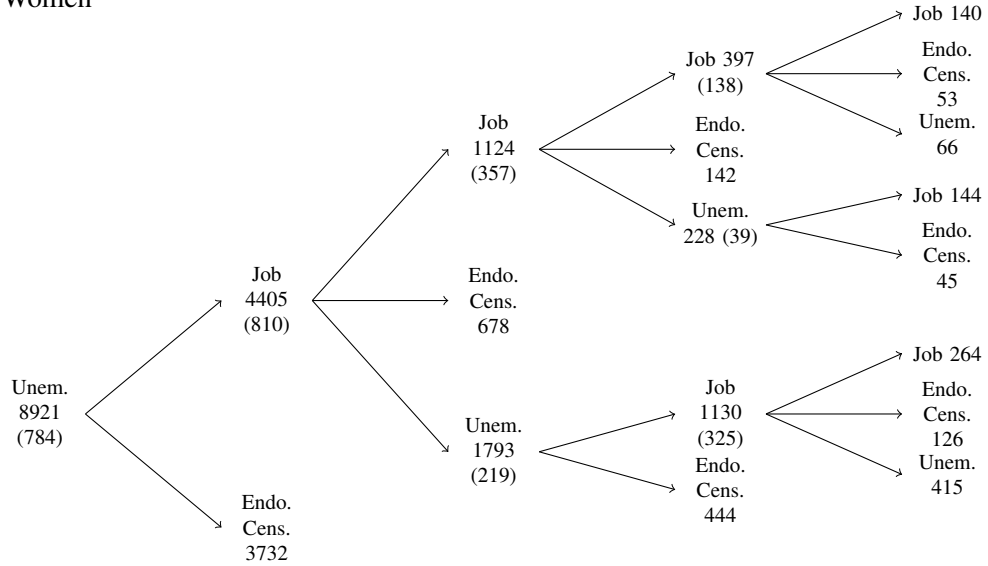

³Note that in these simulations we retain the parameter draw of the first step, so that over these simulations both observed and unobserved characteristics are fixed at individual level.

⁴We follow Davidson and Mackinnon (2004, § 4.6) to construct these confidence intervals.

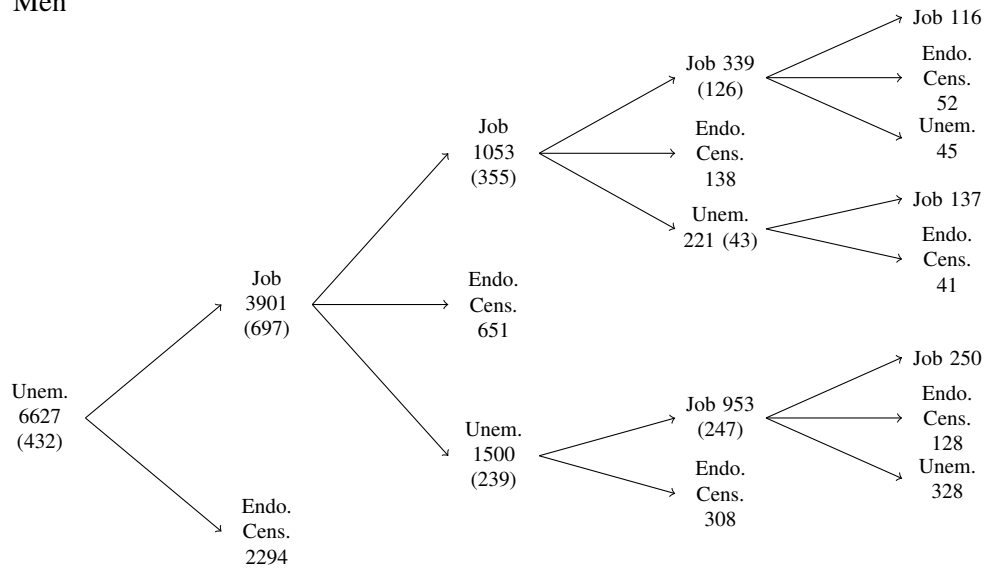

out $d = 4, 7$ quarters after the beginning of the short-lived job. Table A-10 includes OLS estimation results of the empirical counterpart of $\tilde{\Delta}_{8i}(7)$ (stacked over the 119 replications of the simulation algorithm) on the observed and unobserved characteristics fixed at the beginning of the observation period. Table A-11 and Figure A-3 report the CAITT distributions when the treated are those who exited the post-school unemployment event through a job lasting maximum one quarter, independently on whether it ended in unemployment or in a new job. Table A-12 and Figure A-4 show the CAITT distributions when a job lasting one quarter is imposed on *all* the individuals who are still unemployed after one year since graduation. Table A-13 displays estimation results of lagged duration and occurrence dependence of the model where the initial conditions problem is approximated following Heckman (1981). Tables A-14–A-19 contain all the other estimated coefficients of the model where the initial conditions problem is approximated following Heckman (1981). Finally, Tables A-20–A-24 comprise all the estimation results of the benchmark model when individual heterogeneity is neglected.

Notes: In parentheses we report the average probability of having entered a long-lasting job d quarters after a jobs lasting maximum one quarter, conditional on not being endogenously censored yet in the evaluation period and on having entered a job lasting maximum one quarter between the start of the observation window (4 quarters after graduation) and m quarters after graduation.

^(a) See footnote ^(a) of Table 5.

Lagged unemployment duration	-	-		-0.042	.009	***	-0.006	.006	
Previous state: unemployment	-	-		-0.201	.074	***	.428	.087	***
Scaling factors – $\ln c_{ue}^1$ s normalized to zero									
$\ln c_{ue}^2$.258	.082	***	-	-		-	-	
$\ln c_{ue}^3$.430	.089	***	-	-		-	-	
# of observations	8,921			# of spells			20,275		
# of parameters	173			Log-likelihood			-51,368.7		

Notes: * Significant at the 10% level; ** significant at the 5% level; *** significant at the 1% level.

Table A-24: Continuing Table A-23

Variable	Transition			(u, a)			(e, a)			
	Coeff.	S.E.		Coeff.	S.E.		Coeff.	S.E.		
Time-invariant covariates \mathbf{x}_{jk}^0										
Constant	-2.139	.270	***	-2.615	.217	***				
<i>Nationality</i> - Reference: Belgian										
Non-Belgian EU	-.185	.070	***	-.068	.138					
Non EU	-.260	.062	***	-.414	.173	**				
<i>Education</i> - Reference: Higher secondary										
Primary school	-.148	.057	***	.552	.145	***				
Lower secondary	.068	.039	*	.204	.093	**				
Higher education	.326	.051	***	-.144	.084	*				
Other	-.377	.183	**	.592	.351	*				
Unknown	.673	.119	***	-.940	.180	***				
<i>Region of residence</i> - Reference: Wallonia										
Flanders	.235	.059	***	s .168453	.106					
Brussels	.064	.053		.109	.105					
Time-variant spell-specific covariates \mathbf{x}_{jk}^1										
Age	-.024	.010	**	.013	.018					
<i>Household position</i> - Reference: Cohabitant										
Head of household	-.068	.164		.079	.132					
Single	.019	.063		.253	.091	***				
<i>Quarter of entry in the spell</i> - Reference: April-May-June										
January-February-March	.042	.067		.118	.093					
July-August-September	-.149	.055	***	.182	.091	**				
October-November-December	.139	.058	**	-.010	.092					
<i>Firm size</i> - Reference: 500 or more employees										
[1, 20) employees	-	-		-.163	.076	**				
[20, 50) employees	-	-		-.403	.125	***				
[50, 100) employees	-	-		-.030	.138					
[100, 500) employees	-	-		-.182	.095	*				
<i>Sector</i> - Reference: Business services										
Agriculture	-	-		-.113	.379					
Industry & Mining	-	-		-.679	.155	***				
Building & Energy	-	-		-1.061	.382	***				
Wholesale & Retail trade	-	-		-.449	.091	***				
Credit & Insurance	-	-		-.798	.243	***				
Other services & Pub. Adm.	-	-		-.415	.077	***				
Log unemployment benefits	-.089	.169		-	-					
Time-variant covariates \mathbf{x}_{jk}^2										
Local unemployment rate	-1.054	.260	***	-.512	.498					
Lagged duration and occurrence dependence										
Lagged job tenure	.062	.037	*	.030	.030					
Lagged unemployment duration	-	-		.010	.011					
Previous state: unemployment	-	-		-.006	.121
